

# Type I Superconductor

- Many of the elemental metals were found to exhibit zero dc resistance at  $T < T_c$
- The critical temperatures of some superconducting materials, classified as type I superconductors, are given in the following Table.

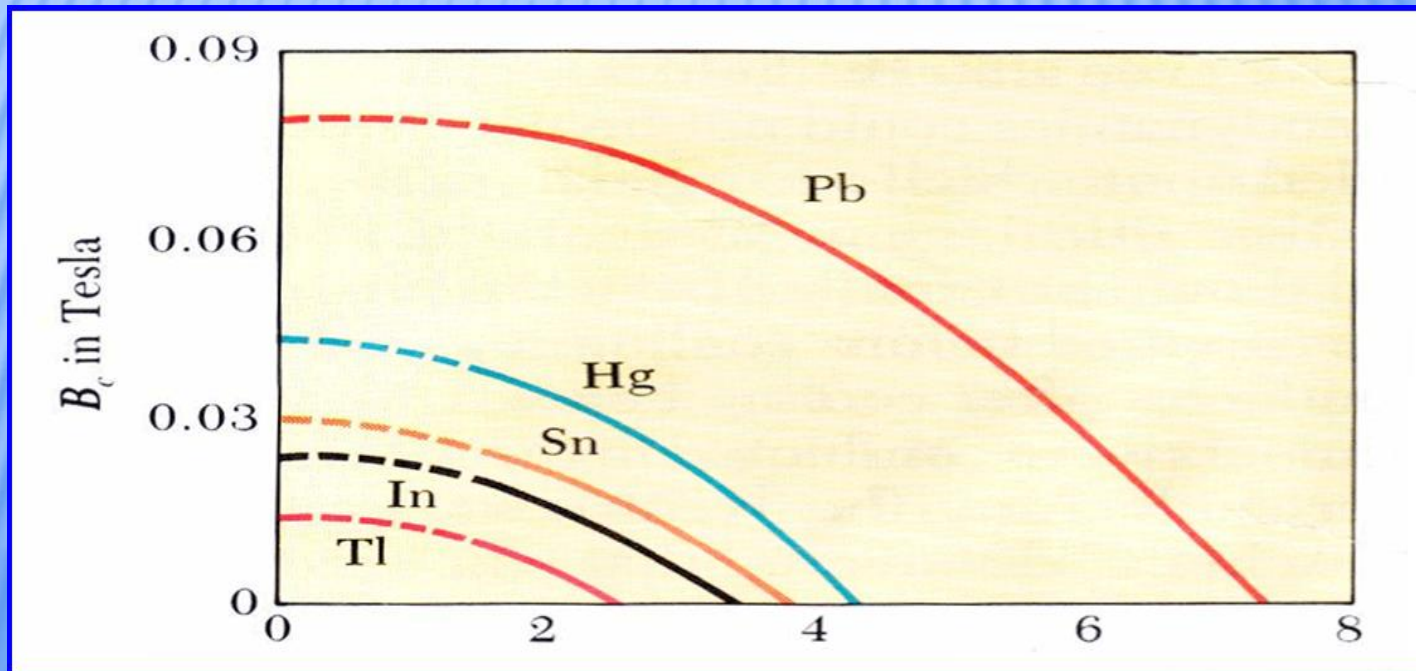

Superconductor	$T_c$ (K)	$B_c$ (O) in Tesla
Al	1.196	0.0105
Ga	1.083	0.0058
H <sub>g</sub>	4.153	0.0411
In	3.408	0.0281
Nb	9.26	0.1991
Pb	7.193	0.0803
Sn	3.722	0.0305
Ta	4.47	0.0829
Ti	0.39	0.010
V	5.30	0.1023
W	0.015	0.000115
Zn	0.85	0.0054

- ❑ As we can see that, Copper (Cu), silver (Ag), and gold (Au), which are excellent conductors, **do not exhibit superconductivity**.
- ❑ We can also notice that, values for the critical field  $B_c$  for type I superconductors are quite low, **less than 0.2 T** as shown in the Table.
- ❑ For this reason, Type I superconductors **cannot be used** to construct high-field magnets, called **superconducting magnets**.

- The critical magnetic field varies with temperature according to the following approximate expression:

$$B_c(T) = B_c(0) \left[ 1 - \left( \frac{T}{T_c} \right)^2 \right]$$

The value of  $B_c(0)$  is found by determining  $B_c$  at some finite temperature, and extrapolating back to  $0\text{ K}$ , which cannot be achieved.

# Magnetic properties of Type I Superconductor

- **In 1933**, Meissner and Ochsenfeld discovered that when a metal becomes superconducting in the presence of a weak magnetic field, the field lines are spontaneously expelled from the interior of the superconductor, by the induction of surface currents, so that  $B = 0$  everywhere interior (**Meissner effect**).

- **Type I Superconductor has the important property of:**
- **Zero dc Resistance (  $R = 0$  )**
- **Perfect Diamagnet (  $B = 0$  ).**

- Demnstration of the Meissner effect is the **Magnetic Levitation**.

## MEISSNER EFFECT

- **Penetration Depth**, due to the formation of surface currents within thin layer (10 ~ 100 nm), the magnetic field **B** inside a **type I** superconductor is:

$$B(x) = B_0 e^{-x/\lambda}$$

**X** : is the distance from the surface, and **λ** : is the penetration depth (~ 10-100 nm),  
**B<sub>0</sub>** : is the value of the magnetic field at the surface.

- The penetration depth varies with temperature according to the empirical expression:

$$\lambda(T) = \lambda_0 \left[ 1 - \left( \frac{T}{T_c} \right)^2 \right]^{-1/2}$$

**λ<sub>0</sub>** : is the penetration depth at **T=0 K**.

- ❖ **Magnetization**, when a bulk sample is placed in an external magnetic field  $B$ , the sample acquires magnetization  $M$ . The magnetic field  $B_{in}$  inside the sample is:

$$B_{in} = B + \mu_0 M$$

- When the sample is in superconducting state,  $B_{in} = 0$ ; therefore the magnetization is given by:

$$M = -\frac{B}{\mu_0} = \chi B$$

where  $\chi = -1/\mu_0$ , is the magnetic susceptibility.

- Therefore, a *type I superconductor exhibits perfect diamagnetism, which is an essential property of the superconducting state.*
